## Module 3: Control Structures in C

# Jumping control-flow statements.

Jumping control-flow statements are the control-flow statements that transfer the control to the specified location or out of the loop or to the beginning of the loop. There are 3 jumping control statements:

# Jumping control-flow statements.

The “**break**” statement is used with in the looping control statements, switch statement and nested loops. When it is used with the for, while or do-while statements, the control comes out of the corresponding loop and continues with the next statement.

Any loop

```
{  
    statement_1;  
    statement_2;  
    :  
    break;  
    :  
}
```

next\_statement

```
#include<stdio.h>  
#include<conio.h>  
  
int main()  
{  
    int i;  
    for(i=1; i<=10; i++)  
    {  
        if(i==6)  
            break;  
        printf("%d",i);  
    }  
    getch();  
}
```

# Jumping control-flow statements.

A **continue statement** is used within loops to **end the execution of the current iteration** and **proceed to the next iteration**. It provides a way of skipping the remaining statements in that iteration after the continue statement.

Any loop

```
{  
    statement_1;  
    statement_2;  
    :  
    continue;  
    :  
}  
next_statement
```

```
#include<conio.h>  
int main()  
{  
    int i, sum=0, n;  
    for(i=1; i<=10; i++)  
    {  
        printf("enter any no:");  
        scanf("%d",&n);  
        if(n<0)  
            continue;  
        else  
            sum=sum+n;  
        printf("%d\n",sum);  
    }  
    getch();  
}
```

# Jumping control-flow statements.

```
int i;  
for (i=0;i<10;i++)  
{  
  
    if (i==5)  
        continue;  
    printf("%d",i);  
    if (i==8)  
        break;  
}
```

# Jumping control-flow statements.

```
int i;  
for (i=0;i<10;i++)  
{  
  
    if (i==5)  
        continue;  
    printf("%d",i);  
    if (i==8)  
        break;  
}
```

This code will print 1 to 8 except 5.

# Jumping control-flow statements.

## Difference Between break and continue:

break	continue
A <code>break</code> can appear in both <code>switch</code> and <code>loop</code> ( <code>for</code> , <code>while</code> , <code>do</code> ) statements.	A <code>continue</code> can appear only in <code>loop</code> ( <code>for</code> , <code>while</code> , <code>do</code> ) statements.
A <code>break</code> causes the <code>switch</code> or <code>loop</code> statements to terminate the moment it is executed. <code>Loop</code> or <code>switch</code> ends abruptly when <code>break</code> is encountered.	A <code>continue</code> doesn't terminate the <code>loop</code> , it causes the <code>loop</code> to go to the next iteration. All iterations of the <code>loop</code> are executed even if <code>continue</code> is encountered. The <code>continue</code> statement is used to skip statements in the <code>loop</code> that appear after the <code>continue</code> .
When a <code>break</code> statement is encountered, it terminates the block and gets the control out of the <code>switch</code> or <code>loop</code> .	When a <code>continue</code> statement is encountered, it gets the control to the next iteration of the <code>loop</code> .
A <code>break</code> causes the innermost enclosing <code>loop</code> or <code>switch</code> to be exited immediately.	A <code>continue</code> inside a <code>loop</code> nested within a <code>switch</code> causes the next <code>loop</code> iteration.

# Jumping control-flow statements.

The **goto statement** transfers the control to the specified location unconditionally. There are certain situations where goto statement makes the program simpler. For example, if a deeply nested loop is to be exited earlier, goto may be used for breaking more than one loop at a time. In this case, a break statement will not serve the purpose because it only exits a single loop.

**label:**

```
{  
statement_1;  
statement_2;  
:  
}
```

**goto label;**

- In this syntax, goto is the keyword and label is any valid identifier and should be ended with a colon (:).
- The identifier following goto is a statement label and need not be declared. The name of the statement or label can also be used as a variable name in the same program if it is declared appropriately.

# Jumping control-flow statements.

## PROGRAM FOR GOTO STATEMENT:

```
#include<stdio.h>
```

```
#include<conio.h>
```

```
void main()
```

```
{
```

```
clrscr();
```

```
printf("www.");
```

```
goto x;
```

```
y:
```

```
printf("expert");
```

```
goto z;
```

```
x:
```

```
printf("c programming");
```

```
goto y;
```

```
z:
```

```
printf(".com");
```

```
getch();
```

```
}
```

3	<b>Control Structures</b>	
	3.1	<b>Decision Making and Branching Control Structures:</b> if Statement, Multiple, Statements within if, if – else Statement, Nested if – else, else if Ladder, Decision making using Switch-Case
	3.2	<b>Looping Control Structures:</b> While Loop, For Loop, Do While Loop, Algorithm and Flowchart for all the loops
	3.3	<b>Jump Statements:</b> Break and Continue, goto Statement
	3.4	<b>Algorithm and Flowchart:</b> Algorithm and Flowchart for if, if-else, else if ladder, switch case, for loop, while loop and do-while loop
